Abstract—The abstract goes here.

I. METHOD

How will you test the hypothesis? What methods will be used from the knowledge learned in state of the art?

The PCB was tested using the National Instruments *myDAQ*, by imposing a square wave with following characteristics:

- Constant 5V amplitude.
- Constant 2.5V positive offset.
- Variable frequency $100Hz - 10kHz$
- Variable duty-cycle 10% – 90%

and then measuring the output

II. RESULTS

What are the results your method have given?

III. CONCLUSION

Have you proven or disproven the hypothesis? If not, why?

IV. DISCUSSION

V. FUTURE WORK

What is the best way to continue the work?

ACKNOWLEDGMENT
